Latitude longitude number format

The Away Luggage Away brand has a habit of keeping its crowds of fans on the ou plains. Known for its washes, highly functional suitcases and travel bags, Away has developed some reputation for cool limited edition collections and colorful collaborations. Last week they started a rainbow cake-inspired collaboration with NYC baker Flour Shop, but are now back at it with something brand new. While they've been holding backpacks and duffle-style bags for quite some time, today he's taken his feat into every day bags to the next level with two brand new tote-style bags. Made of premium leather, these totes - which are appropriately called Length or Width - are elegant enough to transfer to the office and practical enough to become your go-to personal item on a plane. Latitude offers a wide, traditional tote shape that can hold up to a 15-inch laptop, and the length provides a larger shoulder bag shape that can tote laptops up to 13 inches wide. Made with on-the-go types in mind, the bags are equipped with a special detachable tape that fits over the handles of Away's signature for easy travel. Both styles are equipped with a detachable interior zipper and a key clip and are available in a palette of four colours: classic black, forest green, dusty pink and rich wine red. Check out the full range below, then get yours on Away. At these coordinates, Australia is one of the smallest continents in the world. The continent's climate and specific location are often based on its latitude and longitude. In Australia, the southern and eastern parts of the continent are generally moderate, with the summer and winter season. However, the northern part of Australia experiences extreme temperature differences in the summer and winter. Australia is an arid climate country that experiences very moderate rainfall. Tropical rainforests are found in various longitudes and in a 3,000-mile zone between a width of 23.5 degrees north and 23.5 degrees south. The line at 23.5 degrees north is known as the Tropic of Cancer, while 23.5 degrees south is called the Tropic of Capricorn; the area between these lines usually results in a consistent tropical climate because of the sun's location high in the sky. The largest rainforests are found in South America, West Africa and Southeast Asia. Tropical rainforests are found on only 7 percent of the Earth's surface. They are categorized after year-round warm temperatures and high rainfall. Tropical rainforests have only two main seasons: dry season and a soother season. The average temperature in the tropical rainforest is 64 degrees Fahrenheit and the area receives about 100 inches of rain each year. This climate stimulates a region with a complex structure and a diverse number of species. The largest rainforests are the Amazon River Basin, located in the northern part of South America, and the Congo River basin, located on the west coast of central Africa. These rainforests can be found along the Equator at 0 degrees latitude. Smaller tropical rainforests are located in Madagascar, Central America, Australia and the Pacific Islands. What's the location of Los Angeles? It may be relative (about 5,000 km west of New York, for example), but a much more specific measurement is required for a cartographer, pilot, geologist or geographer. To accurately find any place in the world, we use a geographic coordinate system that is measured in degrees of latitude and longitude. This system begins with an imaginary network of lines covering the entire planet. Locations are measured based on X and Y coordinates within the grid. Because the Earth is round, the distances between the lines on the grid vary. The length is defined as imaginary lines called meridians, running from north to south pole. The meridians total 360. The main meridian runs through the Greenwich Observatory in England, a location agreed by a conference in 1884 to be 0 degrees. On the opposite side of the Earth, the international date line is approximately 180 degrees long, although the date line does not follow the exact straight line. (This does not help countries in different days.) When a person crosses an international date line that travels from west to east, one day they move upwards. One day they move back as they travel east to west. Width is defined as an imaginary line called a parallel because they are parallel to the equator and to each other. An equator that runs in a circle around the center of the Earth divides the planet into the northern and southern hemispheres. Latitude and longitude lines are crossed out to create a grid that allows anyone in any location to determine a geographic location. There is 360 degrees longitude (because meridians make large circles around the world), and there is 180 degrees latitude. To pinpoint in detail where to find anything on Earth, measurements are not only in degrees, but also in minutes and seconds. Each level can be broken down into 60 minutes and divided into 60 seconds each minute. Each specific location can be described in terms of degrees, longitude and latitude. Latitude rates are parallel, so for the most part the distance between each stage remains constant. However, the Earth is somewhat elliptical in shape and this creates a small variation between degrees as we work our way from the equator to north and south pole. Each level of latitude is about 100 km (111 miles) apart. At the equator, the distance is 108,703 km (110,567 kilometers). At the Tropic of Cancer and Tropic of Capricorn (23.5 degrees north and south) there is a distance of 108.94 km (110,948 kilometers). Each of the poles has a distance of 100,407 km (111,699 kilometers). It's quite convenient when you want to know how far between each level, no matter where you are on Earth. All you need to know is that every minute (1/60 degree) is about 1.5 km. For example, if we were at 40 degrees north, 100 degrees west, we'd be on the Nebraska-Kansas border. If we went directly north at 41 degrees north, 100 degrees west, we'd have traveled about 109 miles and we'd now be close to Interstate 80. Unlike latitude, the distance between degrees of longitude varies greatly depending on your location on the planet. They're the furthest away from the equator and they gather at the pole. The length level on the equator is widest with a distance of 100,172 km (111,321 kilometers). The distance gradually shrinks to zero when they meet in the pole. At 40 degrees north or south, the distance between the level is 83 miles (85 kilometers). The 40-degree line runs through the middle of the United States and China, as well as Turkey and Spain. Meanwhile, 40 degrees south of Africa, passes through the southern part of Chile and Argentina, and runs almost directly through the center of New Zealand. What if you have two coordinates for latitude and longitude and you need to know how far between the two locations? You could use what's known as the Haversine formula to calculate the distance - unless you're whiz in trigonometry, it's not easy. Fortunately, computers in today's digital world can count on us. Most interactive map applications will allow you to enter latitude and longitude GPS coordinates and tell you the distance between the two points. Multiple latitude/longitude calculators are available online. The National Hurricane Center has one that is very easy to use. Keep in mind that you can also find the exact latitude and longitude of the location with the map app. For example, in Google Maps, you can simply click on a location, and a pop-up window will give data about the width and length per millionth degree. Similarly, you'll get information about the width and length by right-clicking on the location in the Quest folder. Length/length calculator. National Hurricane Center and Central Pacific Hurricane Center. Center.
